2016 Summer Course on Mathematical Modeling and Analysis of Infectious Diseases

National Taiwan University

Goals

- This lecture will explain
 - exponential growth (and decline)
 - simple qualitative methods for analyzing ODE-based dynamical systems
 - the importance of linear equations
 - some basic ideas about matrices and eigenvalues

Outline

Exponential change

Population growth example

Disease mode

Matrices and eigenvalues

Modeling decline

- We have some bacteria in a tank
- They have no food, so they are simply dying at a per capita rate of 0.02/hr.
- If the current density is 100 bacteria/ml, what will be the density after 1 hr?
- What will be the density after 1 wk?

A simple model of population growth

$$\frac{dN}{dt} = rN$$

- This is the only differential equation you need to solve!
- $N(t) = N(0)e^{rt} = N(0) \exp(rt)$
- Bacteria example

Outline

Exponential change

Population growth example

Disease model

Matrices and eigenvalues

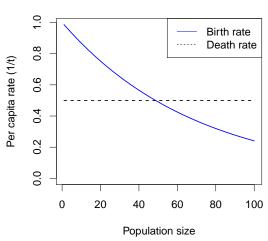

A more realistic model of population growth

- Populations don't grow forever
 - or decline forever
- Probably the birth rate will decline if the population is too crowded
- Let's let the birth rate go down as population goes up:

$$b_0 = (b_0 \exp(-N/N_b) - d)N$$

A model of population growth

A model of population growth

$$b_0 = (b_0 \exp(-N/N_b) - d)N$$

We don't want to solve this equation!

What can we do instead?

- Computer simulations: what will happen with particular parameters?
- Qualitative analysis: what can we learn in general?

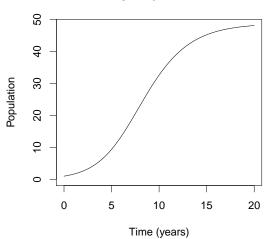

Population growth model

Structure:
$$\frac{dN}{dt} = (b_0 \exp(-N/N_b) - d)N$$

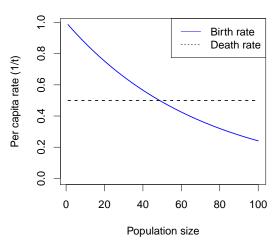

- Parameters?
 - ▶ b₀: per capita birth rate [1/time]
 - d: per capita death rate [1/time]
 - N_b: Scale of population regulation [indiv]
- State variables?
 - N: Population size [indiv]

Computer simulation

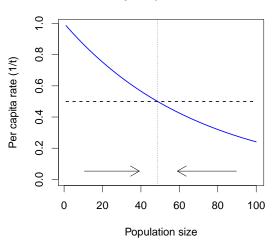

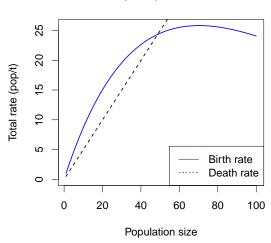

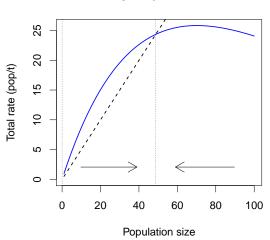

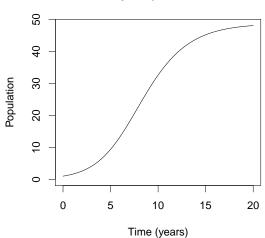

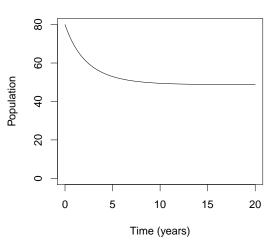

Computer simulation

Computer simulation

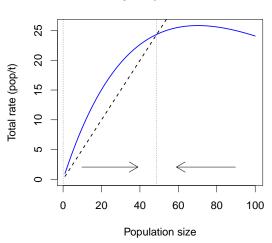

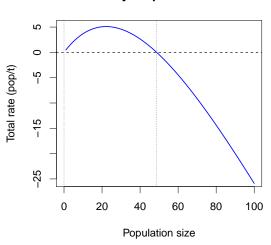

Qualitative analysis

- ► Find *equilibria* points where the population will not change
 - ► Structure: $\frac{dN}{dt} = f(N)$
 - Equilibria when f(N) = 0
- Analyze equilibrium stability if we are near the equilibrium, we will move toward it or away from it?
 - ▶ How does f(N) change near an equilibrium?

Linearization

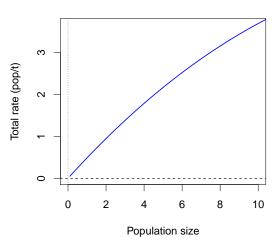

Linearization

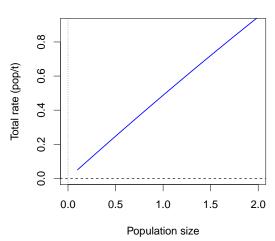

Zoom to extinction equilibrium

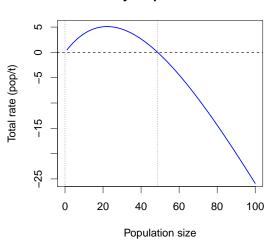

Zoom to extinction equilibrium

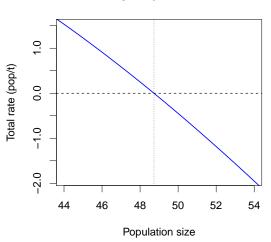

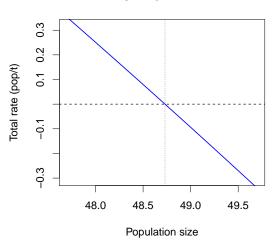

Linearization

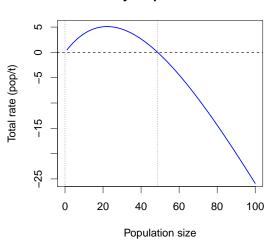

Zoom to carrying capacity

Zoom to carrying capacity

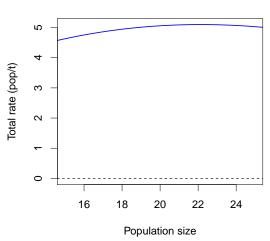

Linearization

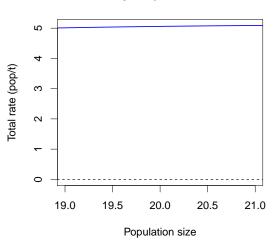

Zoom to other point

Zoom to other point

Linearization

Near an equilibrium, the system behaves like:

$$\frac{dx}{dt} = Jx$$

x is the distance from equilibrium

$$J = \frac{\partial f}{\partial x}$$

- ▶ The solution is $x(t) = x(0) \exp(Jt)$
 - Moves away exponentially if J > 0
 - Moves in exponentially if J < 0</p>

Outline

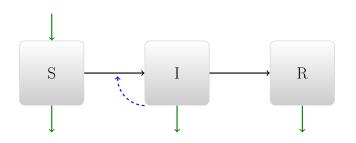

Exponential change

Population growth example

Disease model

Matrices and eigenvalues

What about our simple disease model?

$$\begin{array}{lcl} \frac{dS}{dt} & = & \mu N - \beta \frac{SI}{N} - \mu S \\ \frac{dI}{dt} & = & \beta \frac{SI}{N} - \gamma I - \mu R \\ \frac{dR}{dt} & = & \gamma I - \mu R \end{array}$$

Disease model

- Parameters?
 - μ : Death rate [1/time]
 - \triangleright β : Transmission rate [1/time]
 - γ: Recovery rate [1/time]
 - N: Population size [indiv]
- State variables?
 - S, I, R − but we are going to ignore R
 - ▶ * It does not affect S or I under our assumptions
 - * It is redundant (we know it if we know N, S and I.

Equilibria

- ▶ I = 0, S = N
 - ► The disease-free equilibrium (DFE)
- $S = \gamma/\beta$, I =(something)
 - ► The endemic equilibrium (EE)

Qualitative analysis

$$\frac{dS}{dt} = f(S, I)$$

$$\frac{dI}{dt} = g(S, I)$$

- ▶ We still have linear equations near the equilibrium
- ► This is the only kind of equation we can solve
- Behaviour is determined by

$$J=\left(egin{array}{cc} rac{\partial f}{\partial \mathbf{S}} & rac{\partial f}{\partial \mathbf{I}} \ rac{\partial g}{\partial \mathbf{S}} & rac{\partial g}{\partial \mathbf{I}} \end{array}
ight)$$

Exponential change

Population growth example

Disease mode

Matrices and eigenvalues

Rabbits

- Imagine we have a population of rabbits
 - Baby rabbits become adults after one month
 - Each pair of adult rabbits produces one pair of baby rabbits each month
 - Rabbits never die
- What happens to this population?

Matrix equations

- We describe this as equations for Adult and Baby rabbits:
 - A' = A + B
 - \triangleright B' = A
- In matrix terms, we write:

$$\left(\begin{array}{c}A'\\B'\end{array}\right)=\left(\begin{array}{cc}1&1\\1&0\end{array}\right)\left(\begin{array}{c}A\\B\end{array}\right)$$

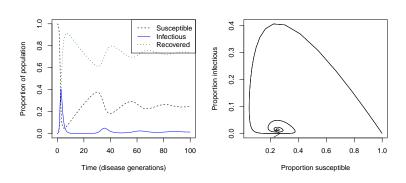

Eigenvectors and eigenvalues

- We describe matrix dynamics using eigenvectors and eigenvalues
 - An eigenvector is a vector which keeps its shape when multiplied by the matrix (it is just multiplied by a regular number)
 - ► An eigenvalue is the number we multiply by

Dominant values

- Usually, matrix dynamics have a single dominant eigenvalue (and eigenvector)
 - This is just the one that is most important for the dynamics we are studying

Disease example

Disease-free equilibrium

- ▶ Dominant eigenvalue is (usually) $\beta \gamma$
 - Describes how fast the epidemic grows exponentially
 - Eigenvector describes relationship between increase in I and decrease in S
- Other eigenvalue describes how fast susceptibles recover to equilibrium when there is no disease

Endemic equilibrium

- There is a pair of complex eigenvalues
 - a + bi, where $i = \sqrt{-1}$
- In complex eigenvalues:
 - ► real part (a) describes exponential growth (or decline)
 - ► imaginary part (b) describes rate of oscillation
